Glossary of Dragonfly and Damselfly.		
Terms and Abbreviations		
Abdomen	The last, and the usually largest, of the three portions of a Dragonfly/damselfly body. It begins	
	after the thorax. It usually is made up of 10 segments	
Abdominal segments	The ten separate parts making up the abdomen . Joints between the segments allow the	
	dragonily to bend easily, this is important when dragoniles mate and lay their eggs. Usually	
	varied patterns of coloration crucial in the identification of certain species	
ΔI	Anterior lamina	
Anal crossing	Cross-yein which links the anal yein and the cubital yein near base of wing Abbr. Cuy	
And crossing	or Ac	
Anal loop	A group of cells enclosed by a thicker vein in the hindwing near the base: not present in all	
	species: the extent of its development and shape useful in the identification of some group.	
	especially gomphids	
Anal margin	Margin of hindwing of Anisoptera, closest to abdomen	
Anal pyramid	Cluster of posterior appendages forming a spiny armature around anus of Anisoptera	
	larvae	
Anal triangle	Found in a few species, a triangle of one or more cells at base of hindwing just below	
	the point where the wing joins the body.	
Anal appendages	Appendages at the tip of male abdomen. (Claspers) (Superior/inferior Appendages)	
A	(Cerci/epiproct Anisoptera) (cerci/paraproct Zygoptera)	
Anal vein	The most posterior (ninth) main longitudinal vein of the wing	
Andromorph	Female form which is similar to the male of the species	
Anteciypeus	Forward-facing area of the face above the labrum and below the postclypeus: in most	
	viewed from above	
Antihumeral string	Name given to the pale lateral stripe along the upperside of thorax	
Antennae	Refers to a pair of feelers on the head which carry sensory organs: poorly develop in	
Antennae	dragonflies. It is thought to aid in the capturing of previat low light and may also serve as	
	airspeed indicators	
Antenodal area	Area of the wing before the nodus between the first (costa) and third (radius) main	
	veins, containing the antenodal Cross-veins (Ax).	
Antenodal Cross-veins	Cross-veins of the leading edge of the wing before the nodus. Abbr. Ax (veins)	
Anterior	towards the front of the Odonata	
Anterior lamina	Protruding lower margin of abdominal segment 2 of true dragonflies (Anisoptera),	
	which forms a lip at the anterior end of the secondary genitalia	
Anisoptera	The group of species that are all true dragonflies .	
Appendages	Backwards-pointing spear- or hook-shaped projections at the tip of the abdomen (there	
	are two pairs: an upper of superior pair (superior appendages) (cerci) and a lower of inferior pair (inferior appendages) (eniprect/Anisontera or paramet/Zygentera)	
Arculus	A major Cross-voin close to the wing base that forms the provinal margin of the	
Arculus	discoidal cell, and which joins the radius vein	
Arthropod	An arthropod is an invertebrate animal having an exoskeleton (external skeleton), a	
	segmented body, and jointed appendages (paired appendages).	
A.s.I	Above sea level	
Auricles (oreillets)	Small, lateral, leaf-like ears on the second abdominal segment of some dragonflies:	
-	they may assist in flight behaviour.	
Ax. Antenodal cross-	Area of the wing before the nodus between the first (costa) and third (radius) main	
vein(s)	veins, containing the antenodal Cross-veins (Ax).	
Brace vein	The vein of the wing immediately posterior to and in line with the inner margin of the	
	pterostigma.	
Bivoltine	(adjective) referring to organisms having two broods or generations per year (Voltism)	
Carina (carinae)	The sharp ridge running longitudinally along the dorsal midline of the synthorax. Also	
Caudal	Toward the end or posterior and of an organism	
Cauda/lamellae	Terminal dill filaments leaf-like projections or of the damselfly larvae (7vgontera) which	
	are usually flat and broad at the tip of the abdomen of Zygoptera larvae	
Cerci	A pair of blade-like or leaf-like structures at the termination of the abdomen of true	
	dragonflies. Also referred to as superior appendage.	
Chin	Casual term for the labium, the lip behind the mandibles which is only visible from below	
Claspers	Male anal appendages (Superior/inferior Appendages) (Cerci/epiproct in	
	Anisoptera) (cerci/paraproct in Zygoptera)	
Clypeus	The area of the face between labrum and frons, made up of the lower anteclypeus and	
	the upper postclypeus (see epitome)	
Collar	Anterior, upturned lip of the prothorax; a ring of hairs around neck	

Complete (Ax vein)	I o be complete the AX vein start at the costa through the subcosta to the radial (R1)
	vein. To incomplete the distal Ax vein does not complete from the subcosta to the radial
	(R1)
Compound eyes	Each compound eye is comprised of several thousand elements known as facets or
	ommatidia. These ommatidia contain light sensitive opsin proteins, thereby functioning as
	the visual sensing element in the compound eye. But unlike humans, day-flying dragonfly
	species have four or five different opsins, allowing them to see colours that are beyond
	human visual capabilities, such as ultraviolet (UV) light. Together, these thousands of
	ommatidia produce a mosaic of "pictures" but how this visual mosaic is integrated in the
	insect brain is still not known.
Costa	Main wing vein that is the leading edge of both the forewings and the hindwings
Costal region	The area along the leading edge of the wings
Cross-veins	Small veins bridging the gap between the main longitudinal veins, which give the wing
	its net-like appearance; important diagnostic Cross-veins include the antenodal Cross-
	veins and the arculus. The term complete means that the vein runs right across either
	side of the 1st radial vein. Abbr. Cux or Ac
Cubital vein (Cux)	The second to last posterior (eighth) main longitudinal vein of the wing Same as (Ac,
	anal crossing)
cuticle	The invertebrate cuticle or cuticula is a multi-layered structure outside the epidermis of many
	invertebrates and arthropods, in which it forms an exoskeleton
Cu2	Second cubital vein
Cux	cubital cross-vein(s) also known as Ac, anal crossing
Coxs or Hip	This part connects the leg to the body.
Damselfly	Insects of the suborder Zygoptera in the order Odonata.
DC	Discoidal Cell (also called the triangle)
Denticles	Tooth-like spines
DF	Discoidal field
Dichromatic/dimorphic	Having two colour/shape forms e.g. 'sexual dimorphic' refers to differences in male 🖒
	and female Q
Discoidal cell	Triangular or quadrangular cell near the base of the wing , the inner side of which is
	formed in part by the arculus
Distal	Furthest away from the body
Dorsal	Upperside of body (opposite to ventral)
Due to the file of	
Dragonity	Insect belonging to the order Odonata , infraorder Anisoptera (from Greek "uneven" and
Dragontiy	Insect belonging to the order Odonata , infraorder Anisoptera (from Greek "uneven" and "wing", because the hindwing is broader than the forewing)
Endemic	Insect belonging to the order Odonata , infraorder Anisoptera (from Greek "uneven" and "wing", because the hindwing is broader than the forewing) With a specified and often restricted geographical range
Endemic Endoskeleton	Insect belonging to the order Odonata , infraorder Anisoptera (from Greek "uneven" and " wing ", because the hindwing is broader than the forewing) With a specified and often restricted geographical range
Endemic Endoskeleton	Insect belonging to the order Odonata , intraorder Anisoptera (from Greek "uneven" and " wing ", because the hindwing is broader than the forewing) With a specified and often restricted geographical range An endoskeleton is a skeleton that is on the inside of a body. The endoskeleton develops within the skin or in the deeper body tissues. The vertebrate endoskeleton is basically made
Endemic Endoskeleton	Insect belonging to the order Odonata , intraorder Anisoptera (from Greek "uneven" and " wing ", because the hindwing is broader than the forewing) With a specified and often restricted geographical range An endoskeleton is a skeleton that is on the inside of a body. The endoskeleton develops within the skin or in the deeper body tissues. The vertebrate endoskeleton is basically made up of two types of tissues (bone and cartilage).
Endemic Endoskeleton Ephemeral rivers	Insect belonging to the order Odonata , intraorder Anisoptera (from Greek "uneven" and " wing ", because the hindwing is broader than the forewing) With a specified and often restricted geographical range An endoskeleton is a skeleton that is on the inside of a body. The endoskeleton develops within the skin or in the deeper body tissues. The vertebrate endoskeleton is basically made up of two types of tissues (bone and cartilage). An enhemeral waterbody is a wetland, spring, stream, river, pond or lake that only exists for a short
Endemic Endoskeleton Ephemeral rivers	Insect belonging to the order Odonata , intraorder Anisoptera (from Greek "uneven" and "wing", because the hindwing is broader than the forewing) With a specified and often restricted geographical range An endoskeleton is a skeleton that is on the inside of a body. The endoskeleton develops within the skin or in the deeper body tissues. The vertebrate endoskeleton is basically made up of two types of tissues (bone and cartilage). An ephemeral waterbody is a wetland, spring, stream, river, pond or lake that only exists for a short period following precipitation or snowmelt. They are not the same as intermittent or seasonal

In usage, some of the larger kinds of exoskeletons are known as " shells ". Examples of animals with exoskeletons include insects such as grasshoppers and cockroaches and Dragonflies . Empty larval shuck left behind on vegetation or rocks after the adult has emerged and flown away (plural: exuviae). (technically, the shell left behind from any molt stage) The main eyes (compound eyes) are the large round structures dominating the head: they are so large because the dragonfly needs good sight as it is a hunter of smaller insects. These eyes are made up of hundreds of small facets, so making the eyes compound. The head also bears 3 tiny, simple eyes (ocelli) on top, arranged in a triangle between the antennae which possibly function as night/day receptors.
Endemic Endoskeleton Ephemeral rivers Epiproct Epistome Exophytic oviposition Exoskeleton Exuvia (Exuviae) Eyes Face	Insect belonging to the order Odonata , infraorder Anisoptera (from Greek "uneven" and "wing", because the hindwing is broader than the forewing) With a specified and often restricted geographical range An endoskeleton is a skeleton that is on the inside of a body. The endoskeleton develops within the skin or in the deeper body tissues. The vertebrate endoskeleton is basically made up of two types of tissues (bone and cartilage). An ephemeral waterbody is a wetland, spring, stream, river, pond or lake that only exists for a short period following precipitation or snowmelt. They are not the same as intermittent or seasonal waterbodies, which exist for longer periods, but not all year round. A triangular, pointed process at the termination of the abdomen in , lying between and below the cerci (superior appendages) Epiproct is also called inferior appendage (Anisoptera) Middle part of the face between the labrum and frons [i.e. clypeus) which is very prominent in Chlorocyphidae Laying eggs onto water or land Is the external skeleton that supports and protects an animal's body, in contrast to the internal skeletons are known as "shells". Examples of animals with exoskeletons include insects such as grasshoppers and cockroaches and Dragonflies . Empty larval shuck left behind on vegetation or rocks after the adult has emerged and flown away (plural: exuviae). (technically, the shell left behind from any molt stage) The main eyes (compound eyes) are the large round structures dominating the head: they are so large because the dragonfly needs good sight as it is a hunter of smaller insects. These eyes are made up of hundreds of small facets, so making the eyes compound. The head also bears 3 tiny, simple eyes (ocelli) on top, arranged in a triangle between the antennae which possibly function as night/day receptors. A casual term for the whole fontal area of the head
Endemic Endoskeleton Ephemeral rivers Epiproct Epistome Exophytic oviposition Exoskeleton Exuvia (Exuviae) Eyes Face Female Ecomut	Insect belonging to the order Odonata , intraorder Anisoptera (from Greek "uneven" and "wing", because the hindwing is broader than the forewing) With a specified and often restricted geographical range An endoskeleton is a skeleton that is on the inside of a body. The endoskeleton develops within the skin or in the deeper body tissues. The vertebrate endoskeleton is basically made up of two types of tissues (bone and cartilage). An ephemeral waterbody is a wetland, spring, stream, river, pond or lake that only exists for a short period following precipitation or snowmelt. They are not the same as intermittent or seasonal waterbodies, which exist for longer periods, but not all year round. A triangular, pointed process at the termination of the abdomen in , lying between and below the cerci (superior appendages) Epiproct is also called inferior appendage (Anisoptera) Middle part of the face between the labrum and frons [i.e. clypeus) which is very prominent in Chlorocyphidae Laying eggs onto water or land Is the external skeleton that supports and protects an animal's body, in contrast to the internal skeleton (endoskeleton) of, for example, a human. In usage, some of the larger kinds of exoskeletons are known as " shells ". Examples of animals with exoskeletons include insects such as grasshoppers and cockroaches and Dragonflies . Empty larval shuck left behind on vegetation or rocks after the adult has emerged and flown away (plural: exuviae). (technically, the shell left behind from any molt stage) The main eyes (compound eyes) are the larger round structures dominating the head: they are so large because the dragonfly needs good sight as it is a hunter of smaller insects. These eyes are made up of hundreds of small facets, so making the eyes compound. The head also bears 3 tiny, simple eyes (ocelli) on top, arranged in a triangle between the antennae which possibly function as night/day receptors. A casual term for the whole frontal area of the head Female shown with symbol \mathfrak
Endemic Endoskeleton Ephemeral rivers Epiproct Epistome Exophytic oviposition Exoskeleton Exuvia (Exuviae) Eyes Face Female Femur	Insect belonging to the order Odonata , intraorder Anisoptera (from Greek "uneven" and "wing", because the hindwing is broader than the forewing) With a specified and often restricted geographical range An endoskeleton is a skeleton that is on the inside of a body. The endoskeleton develops within the skin or in the deeper body tissues. The vertebrate endoskeleton is basically made up of two types of tissues (bone and cartilage). wings)	
Foliations	Flattened, lateral, leaf-like extensions at the tip of the abdomen of some adult Clubtails
	(Gomphidae) and, fe male s of some other species
Forehead	Casual term for the front, top of the head, and mode up variously of port of frons and port
	of vertex
Forewing(s) Fw	First pair of wings. (front wings) Abbr. Fw
Frons	Upward-facing area (in damselflies) or angular (in dragonflies) at the front of the face
	above the postclypeus and in front of the vertex (top of head) and between lower port of
	the eyes
Frontal bond	Forward-facing port of the frons of damselflies, which may be important in the
	identification of some species e.g. Wisps (Agriocnemis)
Genoe	Areas of face between the eyes and the labrum and mandibles
Genus	Members of a family related in structures and heredity that can be further
	divided into species
Gills	A respiratory structure through which oxygen is obtained
Globular	Rounded in shape
Hamule	Hook like projections that are found under abdominal S2 on the male dragonfly. Its function is
	to hold the females genitalia in place during mating. Hamule also same as posterior hamule in
	Macromiidae, Libellulidae
Head	The first of three sections (the other two being thorax and abdomen) bearing important
	sensory organs, especially the large eyes and the mouth
Hindwing(s)	Second pair of wings
Hip or coxs	This part connects the leg to the body.
Humeral stripe	Name given to the pale lateral stripe below the Antihumeral stripe along the upper side of
	thorax.
Hyaline	Means clear or transparent and is used to describe the wings of a dragonfly
Incomplete	Refers to the distal Ax vein that does not complete from the subcosta to the radial To be
	complete the Ax vein start at the costa through the subcosta to the radial (R1) vein.
Inferior appendages	"Epiproct". Lower, terminal, appendages on segment 10 of male damselflies
Instar	A molting or shedding of the larvae exoskeleton. (Larval stage)
Intersegmental	Soft, moveable joints between the segments, especially of the abdomen
membrane	
Invertebrate	Animals that neither possess nor develop a vertebral column (commonly known as a
	backbone or spine). Includes almost all animals Familiar examples of invertebrates include
	insects; (Dragonflies).
IR	Inter-radial veins, numbered1, 2, 3
Labial mask	On Odonata the part of the labium that covers part of the head
Labium	Lower lip, casually referred to as the chin, lying behind the mandibles and only visible
	from below
Labrum	The conspicuous plate, or front 'lip', running across the lower region of the face when
	viewed from the front
Larva	Immature stage of Odonata, larva, nymph, naiad are often used interchangeably to describe
	the intermediate stage of the dragonflies life (between eggs and adult)
Lateral	The side of the Odonata
Lip	The labrum: the bottom port of the face when viewed from the front
Legs	Dragonflies and Damselflies have 3 pairs of legs. Fore-, Mid-, and Hindlegs. Each leg
	has 3 segments. Femur (upper segment), Tibia (mid segment), and Tarsus (final
Mala	Segment). The tarsus ends in the Tarsal claw.
	Pair of pincer-like jaws
Median vein	Starts at the base of the wing and continue as upper side of the triangle and ends below
Malania	The RSpi loop. Abbr. M
	Dark of blackish form
Membranule	A narrow, triangular area on the inside of the hindwing of true dragonflies :
Macanoniatornum	In Odenate, the energiaternum
Macanimeren	In Odonata, the anepistemum.
Mesepinieron	1. The erect of the mean player
(Mosonistorna)	1. The area of the <u>mesopleuron anterior</u> to the mesopleural suture; sometimes <u>divided</u> into an
(wesepisterna)	The lower division of the meanimerer
(Mosonimoro)	
(mesepillera)	The playrap of the magatheraxy in winged insects, compared of baselers, sylholars
(mesopleuro)	mechoisternum, mesonimeron and mesotrochantin
Mesostiamal Jamina	The ridge or flange on the mesostigmal plate of the anterior region of the suntherey
Mosostigmal plata	The muye of nanye on the mesosliginal plate of the anterior region of the synthorax
mesusiigiliai piate	The small plate of science forming the antenor and porsal edge of the synthorax, and

	may bear a ridge or flange (mesostigmal lamina); in the female, this plate is modified in
	accordance with the mole appendages as this is the contact point for tandem linkage in
	Zygoptera
Mesothorax	The middle of the thoracic divisions.
Metepimeral carina	A keel-shaped anatomical part, ridge, or process at the bottom of the thorax side (often
-	marked with a thin black line along the ridge line). On the Epimeron of the Metathorax (the
	lower rear of the thorax)
Moustache	A dark bond running across middle of front of face in Wisps (Agriocnemis spp) (see
	diagram p.26)
Multivoltine.	A multivoltine species is a species that has two or more broods of offspring per year.
	Multivoltine species are often short lived insects such as mosquitoes. They have a short
	adult lifespan and often die soon after mating. The larvae then develop quickly and multiple
	generations occur within a year.
Naiad	Immature stage of Odonata, larva, nymph, naiad are often used interchangeably
	to describe the intermediate stage of the dragonflies life (between eggs and adult)
Neck	Casual term for the prothorax
Nodus	The small kink more or less midway along the anterior, leading edge of the wing, and
	where the sub costa turns forward to meet the costa
Obelisking	In some perching dragonflies, the raising of the abdomen high in the air, sometimes on
_	almost vertical position, to keep cool by presenting minimum area to the sun's rays,
	sometimes while still maintaining a territorial position
Ocelli	Three, simple eyes, arranged in a triangle on the Dorsal surface of the head
Occiput	Top, back of head: often diagnostic in damselflies as it bears the postocular spots
Odonata	The insect order made up of the true dragonflies (Anisoptera) and the damselflies
	(Zygoptera): the term means 'toothed' referring to the strong mandibles of the adult
Ommatidiaum	Compound eyes are composed of units called ommatidia (singular: ommatidium). An
(ommatidia)	ommatidium contains a cluster of photoreceptor cells surrounded by support cells and
	pigment cells. The outer part of the ommatidium is overlaid with a transparent cornea. Each
	ommatidium is innervated by one axon bundle (usually consisting of 6-9 axons, depending
	on the number of rhabdomeres) and provides the brain with one picture element. The brain
	forms an image from these independent picture elements. The number of ommatidia in the
	eye depends upon the type of insect and ranges from just a handful to around 30 thousand in
	larger Anisoptera.
Ovipositor	larger Anisoptera. Egg-laying apparatus in Zygoptera and some Anisoptera
Ovipositor Peaks	Egg-laying apparatus in Zygoptera and some Anisoptera Pair of cone-shapes on the upper surface of front of top of head (vertex) in some true
Ovipositor Peaks	Egg-laying apparatus in Zygoptera and some Anisoptera Pair of cone-shapes on the upper surface of front of top of head (vertex) in some true dragonflies : diagnostic in some Skimmers (Orthetrum)
Ovipositor Peaks Pilosity	Egg-laying apparatus in Zygoptera and some Anisoptera Pair of cone-shapes on the upper surface of front of top of head (vertex) in some true dragonflies : diagnostic in some Skimmers (Orthetrum) A covering of fine 'hairs' or setae
Ovipositor Peaks Pilosity Pleural suture	Iarger Anisoptera. Egg-laying apparatus in Zygoptera and some Anisoptera Pair of cone-shapes on the upper surface of front of top of head (vertex) in some true dragonflies: diagnostic in some Skimmers (Orthetrum) A covering of fine 'hairs' or setae A suture on a thoracic pleuron extending from the base of the wing to the base of the coxa,
Ovipositor Peaks Pilosity Pleural suture (mesopleural suture)	Iarger Anisoptera. Egg-laying apparatus in Zygoptera and some Anisoptera Pair of cone-shapes on the upper surface of front of top of head (vertex) in some true dragonflies: diagnostic in some Skimmers (Orthetrum) A covering of fine 'hairs' or setae A suture on a thoracic pleuron extending from the base of the wing to the base of the coxa, separating the episternum and epimeron; referred to as pro-, meso-, or metapleural ridge.
Ovipositor Peaks Pilosity Pleural suture (mesopleural suture) Polymorphism	Iarger Anisoptera. Egg-laying apparatus in Zygoptera and some Anisoptera Pair of cone-shapes on the upper surface of front of top of head (vertex) in some true dragonflies: diagnostic in some Skimmers (Orthetrum) A covering of fine 'hairs' or setae A suture on a thoracic pleuron extending from the base of the wing to the base of the coxa, separating the episternum and epimeron; referred to as pro-, meso-, or metapleural ridge. Two or more forms within the some species
Ovipositor Peaks Pilosity Pleural suture (mesopleural suture) Polymorphism Postclypeus	Iarger Anisoptera. Egg-laying apparatus in Zygoptera and some Anisoptera Pair of cone-shapes on the upper surface of front of top of head (vertex) in some true dragonflies: diagnostic in some Skimmers (Orthetrum) A covering of fine 'hairs' or setae A suture on a thoracic pleuron extending from the base of the wing to the base of the coxa, separating the episternum and epimeron; referred to as pro-, meso-, or metapleural ridge. Two or more forms within the some species Upward-facing area (top of 'nose') (in damselflies) or forward-facing area of the face
Ovipositor Peaks Pilosity Pleural suture (mesopleural suture) Polymorphism Postclypeus	Iarger Anisoptera. Egg-laying apparatus in Zygoptera and some Anisoptera Pair of cone-shapes on the upper surface of front of top of head (vertex) in some true dragonflies: diagnostic in some Skimmers (Orthetrum) A covering of fine 'hairs' or setae A suture on a thoracic pleuron extending from the base of the wing to the base of the coxa, separating the episternum and epimeron; referred to as pro-, meso-, or metapleural ridge. Two or more forms within the some species Upward-facing area (top of 'nose') (in damselflies) or forward-facing area of the face above the anteclypeus and below the frons
Ovipositor Peaks Pilosity Pleural suture (mesopleural suture) Polymorphism Postclypeus Postnodal	Iarger Anisoptera. Egg-laying apparatus in Zygoptera and some Anisoptera Pair of cone-shapes on the upper surface of front of top of head (vertex) in some true dragonflies: diagnostic in some Skimmers (Orthetrum) A covering of fine 'hairs' or setae A suture on a thoracic pleuron extending from the base of the wing to the base of the coxa, separating the episternum and epimeron; referred to as pro-, meso-, or metapleural ridge. Two or more forms within the some species Upward-facing area (top of 'nose') (in damselflies) or forward-facing area of the face above the anteclypeus and below the frons Beyond the nodus. Usually referring to cross-vein(s) Abbr. Px.
Ovipositor Peaks Pilosity Pleural suture (mesopleural suture) Polymorphism Postclypeus Postnodal Postnodal cross-	Iarger Anisoptera. Egg-laying apparatus in Zygoptera and some Anisoptera Pair of cone-shapes on the upper surface of front of top of head (vertex) in some true dragonflies: diagnostic in some Skimmers (Orthetrum) A covering of fine 'hairs' or setae A suture on a thoracic pleuron extending from the base of the wing to the base of the coxa, separating the episternum and epimeron; referred to as pro-, meso-, or metapleural ridge. Two or more forms within the some species Upward-facing area (top of 'nose') (in damselflies) or forward-facing area of the face above the anteclypeus and below the frons Beyond the nodus. Usually referring to cross-vein(s) Abbr. Px. Cross-vein(s) beyond the nodus Abbr. Px.
Ovipositor Peaks Pilosity Pleural suture (mesopleural suture) Polymorphism Postclypeus Postnodal Postnodal cross- vein(s)	Iarger Anisoptera. Egg-laying apparatus in Zygoptera and some Anisoptera Pair of cone-shapes on the upper surface of front of top of head (vertex) in some true dragonflies: diagnostic in some Skimmers (Orthetrum) A covering of fine 'hairs' or setae A suture on a thoracic pleuron extending from the base of the wing to the base of the coxa, separating the episternum and epimeron; referred to as pro-, meso-, or metapleural ridge. Two or more forms within the some species Upward-facing area (top of 'nose') (in damselflies) or forward-facing area of the face above the anteclypeus and below the frons Beyond the nodus. Usually referring to cross-vein(s) Abbr. Px. Cross-vein(s) beyond the nodus Abbr. Px.
Ovipositor Peaks Pilosity Pleural suture (mesopleural suture) Polymorphism Postclypeus Postnodal Postnodal cross- vein(s) Postocular spots	Iarger Anisoptera. Egg-laying apparatus in Zygoptera and some Anisoptera Pair of cone-shapes on the upper surface of front of top of head (vertex) in some true dragonflies: diagnostic in some Skimmers (Orthetrum) A covering of fine 'hairs' or setae A suture on a thoracic pleuron extending from the base of the wing to the base of the coxa, separating the episternum and epimeron; referred to as pro-, meso-, or metapleural ridge. Two or more forms within the some species Upward-facing area (top of 'nose') (in damselflies) or forward-facing area of the face above the anteclypeus and below the frons Beyond the nodus. Usually referring to cross-vein(s) Abbr. Px. Cross-vein(s) beyond the nodus Abbr. Px. Light-coloured spots on top of the head in some damselflies: diagnostic in Sprites
Ovipositor Peaks Pilosity Pleural suture (mesopleural suture) Polymorphism Postclypeus Postnodal Postnodal Postnodal cross- vein(s) Postocular spots	Iarger Anisoptera. Egg-laying apparatus in Zygoptera and some Anisoptera Pair of cone-shapes on the upper surface of front of top of head (vertex) in some true dragonflies: diagnostic in some Skimmers (Orthetrum) A covering of fine 'hairs' or setae A suture on a thoracic pleuron extending from the base of the wing to the base of the coxa, separating the episternum and epimeron; referred to as pro-, meso-, or metapleural ridge. Two or more forms within the some species Upward-facing area (top of 'nose') (in damselflies) or forward-facing area of the face above the anteclypeus and below the frons Beyond the nodus. Usually referring to cross-vein(s) Abbr. Px. Cross-vein(s) beyond the nodus Abbr. Px. Light-coloured spots on top of the head in some damselflies: diagnostic in Sprites (Pseudagrion)
Ovipositor Peaks Pilosity Pleural suture (mesopleural suture) Polymorphism Postclypeus Postnodal Postnodal cross- vein(s) Postocular spots Prothorax	Iarger Anisoptera. Egg-laying apparatus in Zygoptera and some Anisoptera Pair of cone-shapes on the upper surface of front of top of head (vertex) in some true dragonflies: diagnostic in some Skimmers (Orthetrum) A covering of fine 'hairs' or setae A suture on a thoracic pleuron extending from the base of the wing to the base of the coxa, separating the episternum and epimeron; referred to as pro-, meso-, or metapleural ridge. Two or more forms within the some species Upward-facing area (top of 'nose') (in damselflies) or forward-facing area of the face above the anteclypeus and below the frons Beyond the nodus. Usually referring to cross-vein(s) Abbr. Px. Cross-vein(s) beyond the nodus Abbr. Px. Light-coloured spots on top of the head in some damselflies: diagnostic in Sprites (Pseudagrion) Small, first segment of thorax bearing first pair of legs but no wings, casually referred to as the storm of an insert of the storm of an insert)
Ovipositor Peaks Pilosity Pleural suture (mesopleural suture) Polymorphism Postclypeus Postnodal Postnodal cross- vein(s) Postocular spots Prothorax	Iarger Anisoptera. Egg-laying apparatus in Zygoptera and some Anisoptera Pair of cone-shapes on the upper surface of front of top of head (vertex) in some true dragonflies: diagnostic in some Skimmers (Orthetrum) A covering of fine 'hairs' or setae A suture on a thoracic pleuron extending from the base of the wing to the base of the coxa, separating the episternum and epimeron; referred to as pro-, meso-, or metapleural ridge. 	shaped patch anywhere on the body
Sclerites	Exoskeleton body plates
Secondary genitalia	Accessory genitalia of male damselflies and dragonflies on segments 2 and 3 of the abdomen : important in the identification of many male dragonflies
S(egment)s	An Abbreviation for abdominal segments . There are ten, with S 1 being adjacent to the abdomen end S 10 being the last and bearing the appendages . Abbr. S
Setae	Fine 'heirs'
Semivoltine	(adjective) referring to organisms whose generation time is more than one year (Voltism)
Setose	With many fine 'hair": downy
Shoulder	Upper dorsal area of thorax
Smoky	When wings are vellowish or brownish, especially with increasing age
Spectacled	Having the shape of spectacles or glasses: important diagnostic feature of the frons in
	Skimmers (Orthetrum)
Sternite	One of the plates on the underside of the thorax or abdomen
Subcosta	Second main vein from the anterior edge of the wing, running from wing base to nodus
Subnodus	The veins running towards the back of the wing immediately behind the nodus
Superior appendages	Terminal, upper appendages of the primary genitalia (appendages) (cerci) on the last abdominal segment: they are important in the identification of many damselflies in particular Found on Anisoptera and Zygoptera
Suturallines	Sutures highlighted in a dark colour against a light background
Sutures	Lines of fusion of the skeletal plates of the thorax
Sympatric	Living in the same habitat in the same geographical area
Synoptic	As pertaining to keys, a summary of all characters, rather than a selection of characters used in the more familiar binary keys
Synthorax	Bulk of the thorax , made up of the last two thoracic segments , bearing both pairs of wings and the last two pairs of legs
Tandem linkage	Clasping of the female by the male 's appendages but the pair are not in genital contact
Tarsus (tarsal)	Terminal segment of the leg
Tarsal claw	Claw carried on the final tarsal segment of an insect. There may be more than one claw on
	each tarsus .
Taxonomy	The classification of organisms
Teneral	Freshly-emerged young adult that has a still-soft body. Males in particular have not yet
	developed the characteristic colours of the mature adult and are often very similar to females
	in colour patterning. Tenerals often move away from the water to mature.
Thorax	Thick, middle section of the body consisting principally of large muscles for the wings and
	legs: it is composed of a small, anterior prothorax, and a much larger synthorax
Thorax front	Dorsal, flattish area of the synthorax between the neck and the wing bases
	Middle segment if leg, between the tarsus and the temur.
Iornus	Pointed, back and inside area of the hindwing in some Anisoptera
I riangle	Discoidal cell of Anisoptera
I rue dragonfly	A general term for a dragonfly (Anisoptera) (Order ODONATA (Fabricius, 1793), Suborder ANISOPTERA (Selys, 1854). Damselflies (Suborder ZYGOPTERA (Selys, 1854)) are not regarded as true dragonflies .
Uncrossed	Opposite of 'crossed'; refers to a character state where there is no cross-vein in the discordial cell
Univoltine	(adjective) referring to organisms having one brood or generation per year (Multivoltism)
Vertex	Frontal, top of head: casually referred to, at least in part, as the 'forehead'
Vertebrate	An animal of a large group distinguished by the possession of a backbone or spinal column, including mammals, birds, reptiles, amphibians, and fishes.
Voltinism	Voltinism is a term used in biology to indicate the number of broods or generations of an
	organism in a year. The term is most often applied to insects, and is particularly in use in Odonata where species vary in their voltinism.
	Univoltine – (adjective) referring to organisms having one brood or generation per year
	Bivoltine - (adjective) referring to organisms having two broods or generations per year
	Multivoltine – (adjective) referring to organisms having more than two broods or
	generations per year
	Semivoltine – (adjective) referring to organisms whose generation time is more than one
	year
Vulvar scale	Modified posterior margin of eighth sternite of the female
Wings	Large structures enabling dispersal and prey capture in adults: there are two pairs, the first pair being the forewings and the second pair the hindwings
Waist	Narrowing of the abdomen at segment 3 in some true dragonflies
Zvgoptera	The group of species comprising the damselflies
